

#### What is a Tree

 In computer science, a tree is an abstract model of a hierarchical structure

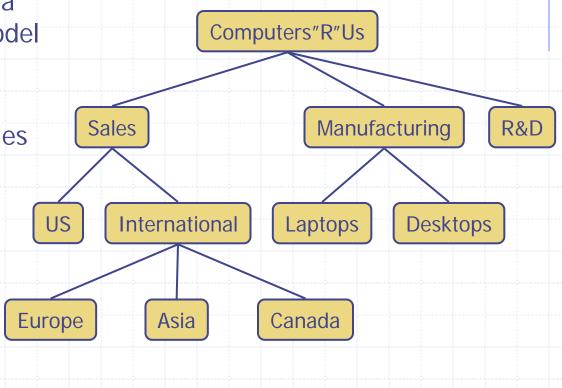

A tree consists of nodes with a parent-child relation

Applications:

Organization charts

File systems

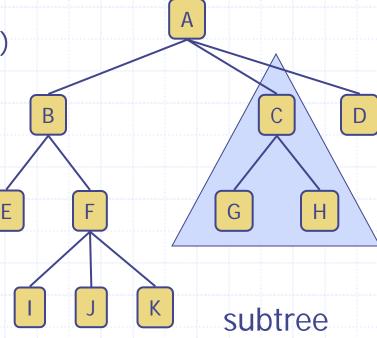

Programming environments

### Tree Terminology

- Root: node without parent (A)
- Internal node: node with at least one child (A, B, C, F)
- External node (a.k.a. leaf ): node without children (E, I, J, K, G, H, D)
- Ancestors of a node: parent, grandparent, grand-grandparent, etc.
- Depth of a node: number of ancestors
- Height of a tree: maximum depth of any node (3)
- Descendant of a node: child, grandchild, grand-grandchild, etc.

 Subtree: tree consisting of a node and its descendants

#### Tree ADT

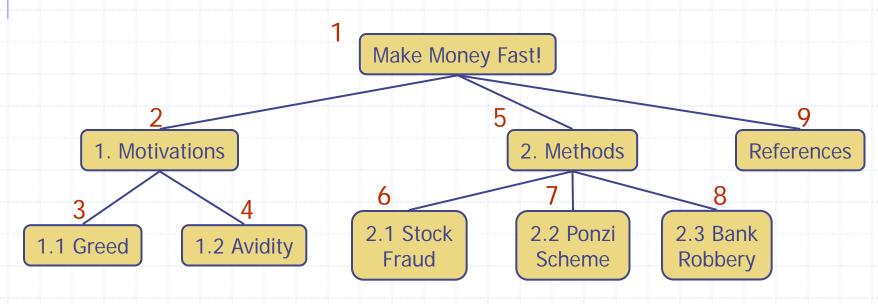

- We use positions to abstract nodes
- Generic methods:
  - integer size()
  - boolean empty()
- Accessor methods:
  - position root()
  - list<position> positions()
- Position-based methods:
  - position p.parent()
  - list<position> p.children()

- Query methods:
  - boolean p.isRoot()
  - boolean p.isExternal()
- Additional update methods may be defined by data structures implementing the Tree ADT

#### **Preorder Traversal**

- A traversal visits the nodes of a tree in a systematic manner
- In a preorder traversal, a node is visited before its descendants
- Application: print a structured document

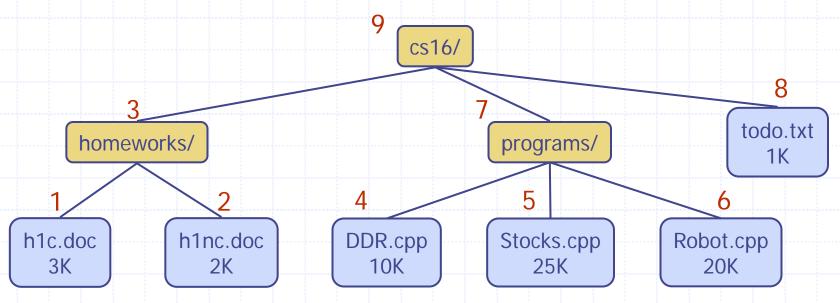

Algorithm preOrder(v)
visit(v)
for each child w of v
preorder (w)

### Postorder Traversal

- In a postorder traversal, a node is visited after its descendants
- Application: compute space used by files in a directory and its subdirectories

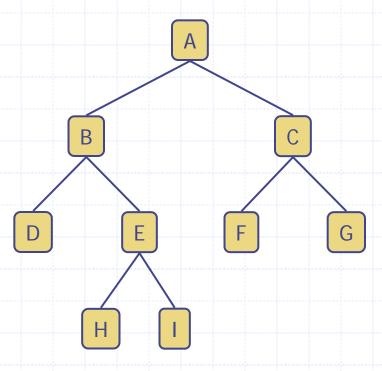

Algorithm postOrder(v)
for each child w of v
postOrder (w)
visit(v)

### Binary Trees

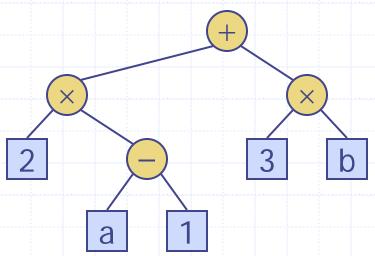

- A binary tree is a tree with the following properties:
  - Each internal node has at most two children (exactly two for proper binary trees)
  - The children of a node are an ordered pair
- We call the children of an internal node left child and right child
- Alternative recursive definition: a binary tree is either
  - a tree consisting of a single node, or
  - a tree whose root has an ordered pair of children, each of which is a binary tree

- Applications:
  - arithmetic expressions
  - decision processes
  - searching

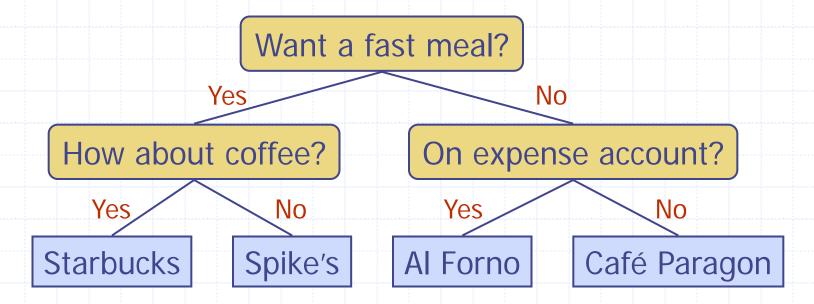

### Arithmetic Expression Tree

- Binary tree associated with an arithmetic expression
  - internal nodes: operators
  - external nodes: operands
- Example: arithmetic expression tree for the expression  $(2 \times (a 1) + (3 \times b))$

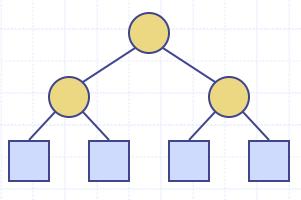

#### **Decision Tree**

- Binary tree associated with a decision process
  - internal nodes: questions with yes/no answer
  - external nodes: decisions
- Example: dining decision

### Properties of Proper Binary Trees

- Notation
  - *n* number of nodes
  - e number of external nodes
  - i number of internal nodes
  - h height

$$e = i + 1$$

$$n = 2e - 1$$

■ 
$$h \leq i$$

■ 
$$h \le (n-1)/2$$

$$e \le 2^h$$

■ 
$$h \ge \log_2 e$$

$$\bullet h \ge \log_2(n+1) - 1$$

## BinaryTree ADT

- The BinaryTree ADT extends the Tree
   ADT, i.e., it inherits all the methods of the Tree ADT
- Additional methods:
  - position p.left()
  - position p.right()

- Update methods may be defined by data structures implementing the BinaryTree ADT
- Proper binary tree:Each node haseither 0 or 2children

#### **Inorder Traversal**

- In an inorder traversal a node is visited after its left subtree and before its right subtree
- Application: draw a binary tree
  - x(v) = inorder rank of v
  - y(v) = depth of v

Algorithm *inOrder(v)* 

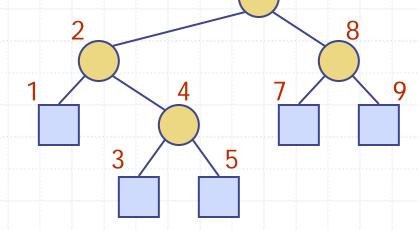

if  $\neg v.isExternal()$ 

inOrder(v.left())

visit(v)

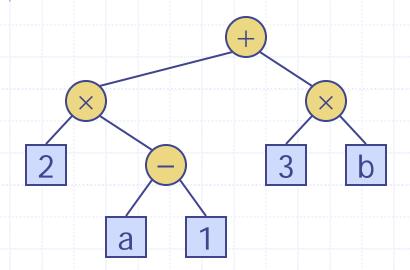

if  $\neg v.isExternal()$ 

inOrder(v.right())

### Print Arithmetic Expressions

- Specialization of an inorder traversal
  - print operand or operator when visiting node
  - print "(" before traversing left subtree
  - print ")" after traversing right subtree

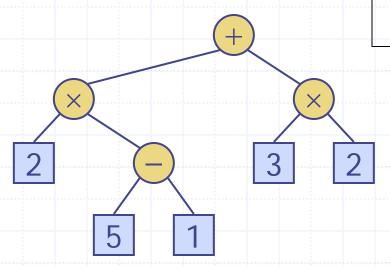

#### Algorithm *printExpression(v)*

$$((2 \times (a - 1)) + (3 \times b))$$

### **Evaluate Arithmetic Expressions**

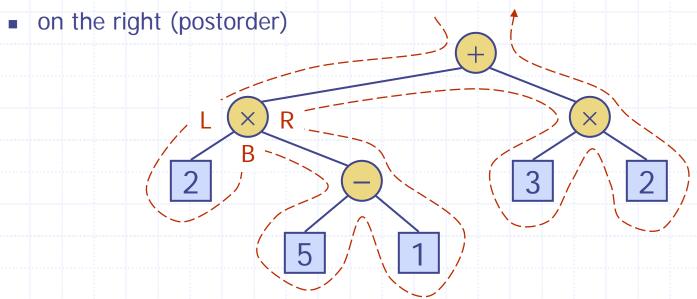

- Specialization of a postorder traversal
  - recursive method returning the value of a subtree
  - when visiting an internal node, combine the values of the subtrees

```
Algorithm evalExpr(v)
if v.isExternal()
return v.element()
else
x \leftarrow evalExpr(v.left())
y \leftarrow evalExpr(v.right())
\Diamond \leftarrow \text{operator stored at } v
return x \Diamond y
```

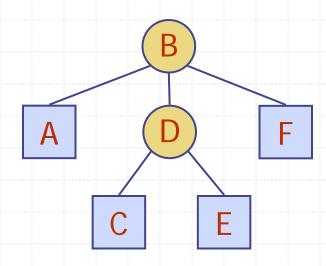

### **Euler Tour Traversal**

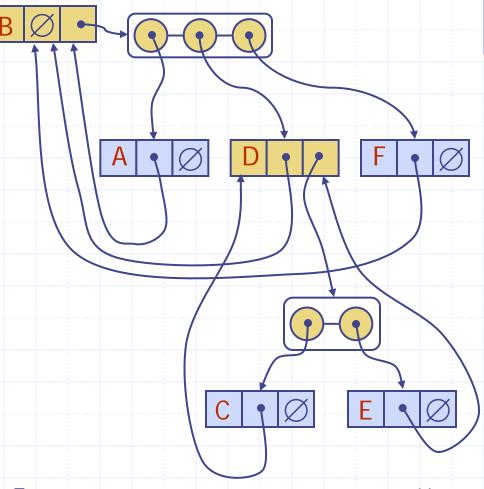

- Generic traversal of a binary tree
- Includes a special cases the preorder, postorder and inorder traversals
- Walk around the tree and visit each node three times:
  - on the left (preorder)
  - from below (inorder)

#### Linked Structure for Trees

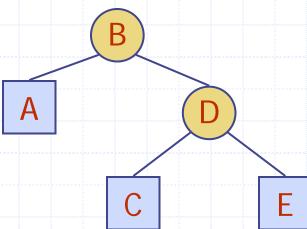

- A node is represented by an object storing
  - Element
  - Parent node
  - Sequence of children nodes
- Node objects implement the Position ADT

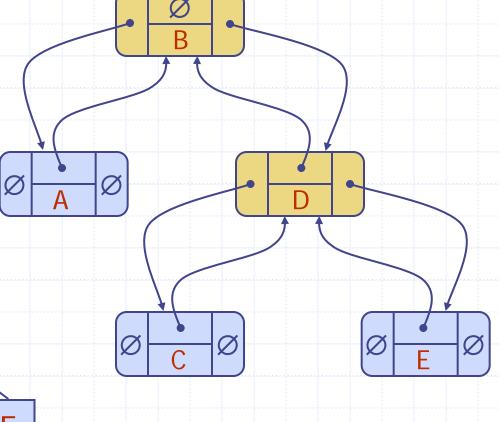

### Linked Structure for Binary Trees

- A node is represented by an object storing
  - Element
  - Parent node
  - Left child node
  - Right child node
- Node objects implement the Position ADT
